Searching

Properties		Linear Search	Binary Search
Definition		Linear search is a sequential searching algorithm where we start from one end and check every element of the list until the desired element is found.	Binary Search is defined as a searching algorithm used in a sorted array by repeatedly dividing the search interval in half.
Time Complexity	Best	0(1)	0(1)
	Average	O(n)	$O(\log n)$
	Worst	O(n)	$O(\log n)$
Space Complexity		0(1)	0(1)
Applications		• For searching operations in smaller arrays (<100 items).	 In libraries of Java, .Net, C++ STL. While debugging, the binary search is used to pinpoint the place where the error happens. Binary search can be used as a building block for more complex algorithms used in machine learning, such as algorithms for training neural networks or finding the optimal hyperparameters for a model. It can be used for searching in computer graphics such as algorithms for ray tracing or texture mapping. It can be used for searching a database.
Advantages		 Linear search can be used irrespective of whether the array is sorted or not. It can be used on arrays of any data type. Does not require any additional memory. It is a well-suited algorithm for small datasets. 	
Disadvantages		 Linear search has a time complexity of O(n), which in turn makes it slow for large datasets. Not suitable for large arrays. 	 The array should be sorted. Binary search requires that the data structure being searched be stored in contiguous memory locations. Binary search requires that the elements of the array be comparable, meaning that they must be able to be ordered.
